

EXERCISE 4.1 PAGE: 94

Prove the following by using the principle of mathematical induction for all $n \in N$: 1.

$$1+3+3^2+...+3^{n-1}=\frac{\left(3^n-1\right)}{2}$$

Solution:

We can write the given statement as

P(n): 1 + 3 + 3² + ... + 3ⁿ⁻¹ =
$$\frac{(3^n - 1)}{2}$$

If n = 1 we get

P(1):
$$1 = \frac{(3^1 - 1)}{2} = \frac{3 - 1}{2} = \frac{2}{2} = 1$$

Which is true.

Consider P (k) be true for some positive integer k

$$1+3+3^2+...+3^{k-1}=\frac{\left(3^k-1\right)}{2}$$
 ...(i)

Now let us prove that P(k+1) is true.

Here

$$1 + 3 + 3^{2} + ... + 3^{k-1} + 3^{(k+1)-1} = (1 + 3 + 3^{2} + ... + 3^{k-1}) + 3^{k}$$

By using equation (i)

$$=\frac{\left(3^{k}-1\right)}{2}+3^{k}$$

Taking LCM

$$=\frac{(3^k-1)+2.3^k}{2}$$

Taking the common terms out

$$=\frac{(1+2)3^k-1}{2}$$

We get

$$=\frac{3.3^k-1}{2}$$

$$=\frac{3^{k+1}-1}{2}$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

2.

$$1^3 + 2^3 + 3^3 + ... + n^3 = \left(\frac{n(n+1)}{2}\right)^2$$

Solution:

We can write the given statement as

P(n):
$$1^3 + 2^3 + 3^3 + ... + n^3 = \left(\frac{n(n+1)}{2}\right)^2$$

If n = 1 we get

P(1):
$$1^3 = 1 = \left(\frac{1(1+1)}{2}\right)^2 = \left(\frac{1.2}{2}\right)^2 = 1^2 = 1$$

Which is true.

Consider P (k) be true for some positive integer k

$$1^3 + 2^3 + 3^3 + \dots + k^3 = \left(\frac{k(k+1)}{2}\right)^2$$
 ... (i)

Now let us prove that P(k+1) is true.

Here

$$1^3 + 2^3 + 3^3 + \dots + k^3 + (k+1)^3 = (1^3 + 2^3 + 3^3 + \dots + k^3) + (k+1)^3$$

By using equation (i)

$$= \left(\frac{k(k+1)}{2}\right)^2 + (k+1)^3$$

So we get

$$= \frac{k^2 (k+1)^2}{4} + (k+1)^3$$

Taking LCM

$$=\frac{k^{2}(k+1)^{2}+4(k+1)^{3}}{4}$$

Taking the common terms out

$$=\frac{\left(k+1\right)^{2}\left\{k^{2}+4\left(k+1\right)\right\}}{4}$$

We get

$$=\frac{\left(k+1\right)^{2}\left\{k^{2}+4k+4\right\}}{4}$$

$$=\frac{(k+1)^2(k+2)^2}{4}$$

By expanding using formula

$$=\frac{(k+1)^{2}(k+1+1)^{2}}{4}$$

$$= \left(\frac{(k+1)(k+1+1)}{2}\right)^2$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

$$1 + \frac{1}{(1+2)} + \frac{1}{(1+2+3)} + \dots + \frac{1}{(1+2+3+\dots n)} = \frac{2n}{(n+1)}$$

We can write the given statement as

P(n):
$$1 + \frac{1}{1+2} + \frac{1}{1+2+3} + \dots + \frac{1}{1+2+3+\dots n} = \frac{2n}{n+1}$$

If n = 1 we get

P(1):
$$1 = \frac{2.1}{1+1} = \frac{2}{2} = 1$$

Which is true.

Consider P (k) be true for some positive integer k

$$1 + \frac{1}{1+2} + \dots + \frac{1}{1+2+3} + \dots + \frac{1}{1+2+3+\dots+k} = \frac{2k}{k+1}$$
 ... (i)

Now let us prove that P(k + 1) is true.

Here

$$1 + \frac{1}{1+2} + \frac{1}{1+2+3} + \dots + \frac{1}{1+2+3+\dots+k} + \frac{1}{1+2+3+\dots+k+(k+1)}$$

$$= \left(1 + \frac{1}{1+2} + \frac{1}{1+2+3} + \dots + \frac{1}{1+2+3+\dots+k}\right) + \frac{1}{1+2+3+\dots+k+(k+1)}$$

By using equation (i)

$$= \frac{2k}{k+1} + \frac{1}{1+2+3+\dots+k+(k+1)}$$

We know that

$$1+2+3+...+n = \frac{n(n+1)}{2}$$

So we get

$$= \frac{2k}{k+1} + \frac{1}{\left(\frac{(k+1)(k+1+1)}{2}\right)}$$

It can be written as

$$= \frac{2k}{(k+1)} + \frac{2}{(k+1)(k+2)}$$

Taking the common terms out

$$=\frac{2}{(k+1)}\left(k+\frac{1}{k+2}\right)$$

By taking LCM

By taking LCM
$$= \frac{2}{k+1} \left(\frac{k(k+2)+1}{k+2} \right)$$

We get

$$= \frac{2}{(k+1)} \left(\frac{k^2 + 2k + 1}{k+2} \right)$$

$$=\frac{2\cdot(k+1)^2}{(k+1)(k+2)}$$

$$=\frac{2(k+1)}{(k+2)}$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

4.

1.2.3 + 2.3.4 + ... +
$$n(n + 1)(n + 2) = \frac{n(n+1)(n+2)(n+3)}{4}$$

Solution:

We can write the given statement as

P(n): 1.2.3 + 2.3.4 + ... +
$$n(n + 1)(n + 2) = \frac{n(n+1)(n+2)(n+3)}{4}$$

If n = 1 we get

P(1): 1.2.3 = 6 =
$$\frac{1(1+1)(1+2)(1+3)}{4}$$
 = $\frac{1.2.3.4}{4}$ = 6

Which is true.

Consider P (k) be true for some positive integer k

1.2.3 + 2.3.4 + ... +
$$k(k+1)(k+2) = \frac{k(k+1)(k+2)(k+3)}{4}$$
 ... (i)

Now let us prove that P(k + 1) is true.

Here

$$1.2.3 + 2.3.4 + ... + k(k+1)(k+2) + (k+1)(k+2)(k+3) = \{1.2.3 + 2.3.4 + ... + k(k+1)(k+2)\} + (k+1)(k+2)(k+3)$$

By using equation (i)

$$=\frac{k(k+1)(k+2)(k+3)}{4}+(k+1)(k+2)(k+3)$$

So we get

$$=(k+1)(k+2)(k+3)(\frac{k}{4}+1)$$

It can be written as

$$=\frac{(k+1)(k+2)(k+3)(k+4)}{4}$$

By further simplification

$$=\frac{(k+1)(k+1+1)(k+1+2)(k+1+3)}{4}$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

5.

$$1.3 + 2.3^{2} + 3.3^{3} + ... + n.3^{n} = \frac{(2n-1)3^{n+1} + 3}{4}$$

Solution:

We can write the given statement as

P(n):
$$1.3 + 2.3^2 + 3.3^3 + ... + n3^n = \frac{(2n-1)3^{n+1} + 3}{4}$$

If n = 1 we get

P(1):
$$1.3 = 3 = \frac{(2.1-1)3^{1+1} + 3}{4} = \frac{3^2 + 3}{4} = \frac{12}{4} = 3$$

Which is true.

Consider P (k) be true for some positive integer k

$$1.3 + 2.3^{2} + 3.3^{3} + \dots + k3^{k} = \frac{(2k-1)3^{k+1} + 3}{4} \qquad \dots (i)$$

Now let us prove that P(k + 1) is true.

Here

$$1.3 + 2.3^2 + 3.3^3 + ... + k3^k + (k+1)3^{k+1} = = (1.3 + 2.3^2 + 3.3^3 + ... + k.3^k) + (k+1)3^{k+1}$$

By using equation (i)

$$=\frac{(2k-1)3^{k+1}+3}{4}+(k+1)3^{k+1}$$

By taking LCM

$$=\frac{(2k-1)3^{k+1}+3+4(k+1)3^{k+1}}{4}$$

Taking the common terms out

$$=\frac{3^{k+1}\left\{2k-1+4(k+1)\right\}+3}{4}$$

By further simplification

$$=\frac{3^{k+1}\left\{6k+3\right\}+3}{4}$$

Taking 3 as common

$$=\frac{3^{k+1}.3\left\{2k+1\right\}+3}{4}$$

$$=\frac{3^{(k+1)+1}\left\{2k+1\right\}+3}{4}$$

$$=\frac{\left\{2\left(k+1\right)-1\right\}3^{(k+1)+1}+3}{4}$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

6.

$$1.2 + 2.3 + 3.4 + ... + n.(n+1) = \left[\frac{n(n+1)(n+2)}{3}\right]$$

We can write the given statement as

P(n):
$$1.2 + 2.3 + 3.4 + ... + n.(n+1) = \left[\frac{n(n+1)(n+2)}{3}\right]$$

If n = 1 we get

P(1):
$$1.2 = 2 = \frac{1(1+1)(1+2)}{3} = \frac{1.2.3}{3} = 2$$

Which is true.

Consider P (k) be true for some positive integer k

$$1.2 + 2.3 + 3.4 + \dots + k.(k+1) = \left[\frac{k(k+1)(k+2)}{3}\right] \dots (i)$$

Now let us prove that P(k+1) is true.

Here

$$1.2 + 2.3 + 3.4 + ... + k.(k+1) + (k+1).(k+2) = [1.2 + 2.3 + 3.4 + ... + k.(k+1)] + (k+1).(k+2)$$

By using equation (i)

$$= \frac{k(k+1)(k+2)}{3} + (k+1)(k+2)$$

We can write it as

$$=(k+1)(k+2)(\frac{k}{3}+1)$$

We get

$$=\frac{(k+1)(k+2)(k+3)}{3}$$

By further simplification

$$=\frac{(k+1)(k+1+1)(k+1+2)}{3}$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

7.

$$1.3+3.5+5.7+...+(2n-1)(2n+1)=\frac{n(4n^2+6n-1)}{3}$$

We can write the given statement as

P(n):
$$1.3+3.5+5.7+...+(2n-1)(2n+1)=\frac{n(4n^2+6n-1)}{3}$$

If n = 1 we get

$$P(1):1.3=3=\frac{1(4.1^2+6.1-1)}{3}=\frac{4+6-1}{3}=\frac{9}{3}=3$$

Which is true.

Consider P (k) be true for some positive integer k

$$1.3 + 3.5 + 5.7 + \dots + (2k-1)(2k+1) = \frac{k(4k^2 + 6k - 1)}{3} \dots (i)$$

Now let us prove that P(k + 1) is true.

Here

$$(1.3+3.5+5.7+...+(2k-1)(2k+1)+\{2(k+1)-1\}\{2(k+1)+1\}$$

By using equation (i)

$$= \frac{k(4k^2+6k-1)}{3} + (2k+2-1)(2k+2+1)$$

$$=\frac{k(4k^2+6k-1)}{3}+(2k+2-1)(2k+2+1)$$

On further calculation

$$= \frac{k(4k^2+6k-1)}{3} + (2k+1)(2k+3)$$

By multiplying the terms

$$=\frac{k(4k^2+6k-1)}{3}+(4k^2+8k+3)$$

Taking LCM

$$=\frac{k(4k^2+6k-1)+3(4k^2+8k+3)}{3}$$

By further simplification

$$=\frac{4k^3+6k^2-k+12k^2+24k+9}{3}$$

So we get

$$=\frac{4k^3+18k^2+23k+9}{3}$$

It can be written as

$$=\frac{4k^3+14k^2+9k+4k^2+14k+9}{3}$$

$$=\frac{k(4k^2+14k+9)+1(4k^2+14k+9)}{3}$$

Separating the terms

$$=\frac{(k+1)\{4k^2+8k+4+6k+6-1\}}{3}$$

Taking the common terms out

$$=\frac{(k+1)\{4(k^2+2k+1)+6(k+1)-1\}}{3}$$

Using the formula

$$=\frac{(k+1)\{4(k+1)^2+6(k+1)-1\}}{3}$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

8. $1.2 + 2.2^2 + 3.2^2 + ... + n.2^n = (n-1) 2^{n+1} + 2$ Solution:

We can write the given statement as

P(n):
$$1.2 + 2.2^2 + 3.2^2 + ... + n.2^n = (n-1) 2^{n+1} + 2$$

If n = 1 we get

P (1):
$$1.2 = 2 = (1 - 1) 2^{1+1} + 2 = 0 + 2 = 2$$
 Which

is true.

Consider P (k) be true for some positive integer k

$$1.2 + 2.2^2 + 3.2^2 + \dots + k.2^k = (k-1)2^{k+1} + 2\dots$$
 (i) Now

let us prove that P(k+1) is true.

Here

$$\{1.2+2.2^2+3.2^3+...+k.2^k\}+(k+1)\cdot 2^{k+1}$$

By using equation (i)

$$=(k-1)2^{k+1}+2+(k+1)2^{k+1}$$

Taking the common terms out

$$=2^{k+1}\{(k-1)+(k+1)\}+2$$

So we get

$$=2^{k+1}.2k+2$$

It can be written as

$$= k.2^{(k+1)+1} + 2$$

$$= \{(k+1)-1\} 2^{(k+1)+1} + 2$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

$$\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \dots + \frac{1}{2^n} = 1 - \frac{1}{2^n}$$

Solution:

We can write the given statement as

P(n):
$$\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + ... + \frac{1}{2^n} = 1 - \frac{1}{2^n}$$

If n = 1 we get

P(1):
$$\frac{1}{2} = 1 - \frac{1}{2^1} = \frac{1}{2}$$

Which is true.

Consider P (k) be true for some positive integer k

$$\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \dots + \frac{1}{2^k} = 1 - \frac{1}{2^k}$$
 ... (i)

Now let us prove that P(k+1) is true.

Here

$$\left(\frac{1}{2} + \frac{1}{4} + \frac{1}{8} + \dots + \frac{1}{2^k}\right) + \frac{1}{2^{k+1}}$$

By using equation (i)

$$= \left(1 - \frac{1}{2^k}\right) + \frac{1}{2^{k+1}}$$

We can write it as

$$=1-\frac{1}{2^k}+\frac{1}{2\cdot 2^k}$$

Taking the common terms out

$$=1-\frac{1}{2^{k}}\left(1-\frac{1}{2}\right)$$

So we get

$$=1-\frac{1}{2^{k}}\left(\frac{1}{2}\right)$$

It can be written as

$$=1-\frac{1}{2^{k+1}}$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

10.

$$\frac{1}{2.5} + \frac{1}{5.8} + \frac{1}{8.11} + \dots + \frac{1}{(3n-1)(3n+2)} = \frac{n}{(6n+4)}$$

Solution:

We can write the given statement as

P(n):
$$\frac{1}{2.5} + \frac{1}{5.8} + \frac{1}{8.11} + \dots + \frac{1}{(3n-1)(3n+2)} = \frac{n}{(6n+4)}$$

If n = 1 we get

$$P(1) = \frac{1}{2.5} = \frac{1}{10} = \frac{1}{6.1 + 4} = \frac{1}{10}$$

Which is true.

Consider P (k) be true for some positive integer k

$$\frac{1}{2.5} + \frac{1}{5.8} + \frac{1}{8.11} + \dots + \frac{1}{(3k-1)(3k+2)} = \frac{k}{6k+4}$$
 ... (i)

Now let us prove that P(k+1) is true.

Here

$$\frac{1}{2.5} + \frac{1}{5.8} + \frac{1}{8.11} + \dots + \frac{1}{(3k-1)(3k+2)} + \frac{1}{\{3(k+1)-1\}\{3(k+1)+2\}}$$

By using equation (i)

$$=\frac{k}{6k+4}+\frac{1}{(3k+3-1)(3k+3+2)}$$

By simplification of terms

$$= \frac{k}{6k+4} + \frac{1}{(3k+2)(3k+5)}$$

Taking 2 as common

$$= \frac{k}{2(3k+2)} + \frac{1}{(3k+2)(3k+5)}$$

Taking the common terms out

$$= \frac{1}{(3k+2)} \left(\frac{k}{2} + \frac{1}{3k+5} \right)$$

Taking LCM

$$= \frac{1}{(3k+2)} \left(\frac{k(3k+5)+2}{2(3k+5)} \right)$$

By multiplication

$$= \frac{1}{(3k+2)} \left(\frac{3k^2 + 5k + 2}{2(3k+5)} \right)$$

Separating the terms

$$= \frac{1}{(3k+2)} \left(\frac{(3k+2)(k+1)}{2(3k+5)} \right)$$

By further calculation

$$=\frac{\left(k+1\right)}{6k+10}$$

So we get

$$=\frac{\left(k+1\right)}{6\left(k+1\right)+4}$$

P(k + 1) is true whenever P(k) is true.

$$\frac{1}{1.2.3} + \frac{1}{2.3.4} + \frac{1}{3.4.5} + \dots + \frac{1}{n(n+1)(n+2)} = \frac{n(n+3)}{4(n+1)(n+2)}$$

Solution:

We can write the given statement as

P(n):
$$\frac{1}{1.2.3} + \frac{1}{2.3.4} + \frac{1}{3.4.5} + \dots + \frac{1}{n(n+1)(n+2)} = \frac{n(n+3)}{4(n+1)(n+2)}$$

If n = 1 we get

$$P(1): \frac{1}{1 \cdot 2 \cdot 3} = \frac{1 \cdot (1+3)}{4(1+1)(1+2)} = \frac{1 \cdot 4}{4 \cdot 2 \cdot 3} = \frac{1}{1 \cdot 2 \cdot 3}$$

Which is true.

Consider P (k) be true for some positive integer k

$$\frac{1}{1 \cdot 2 \cdot 3} + \frac{1}{2 \cdot 3 \cdot 4} + \frac{1}{3 \cdot 4 \cdot 5} + \dots + \frac{1}{k(k+1)(k+2)} = \frac{k(k+3)}{4(k+1)(k+2)}$$
 ... (i)

Now let us prove that P(k+1) is true.

Here

$$\left[\frac{1}{1\cdot 2\cdot 3} + \frac{1}{2\cdot 3\cdot 4} + \frac{1}{3\cdot 4\cdot 5} + \dots + \frac{1}{k(k+1)(k+2)}\right] + \frac{1}{(k+1)(k+2)(k+3)}$$

By using equation (i)

$$= \frac{k(k+3)}{4(k+1)(k+2)} + \frac{1}{(k+1)(k+2)(k+3)}$$

Taking out the common terms

$$= \frac{1}{(k+1)(k+2)} \left\{ \frac{k(k+3)}{4} + \frac{1}{k+3} \right\}$$

Taking LCM

$$= \frac{1}{(k+1)(k+2)} \left\{ \frac{k(k+3)^2 + 4}{4(k+3)} \right\}$$

Expanding using formula

$$= \frac{1}{(k+1)(k+2)} \left\{ \frac{k(k^2+6k+9)+4}{4(k+3)} \right\}$$

By further calculation

$$= \frac{1}{(k+1)(k+2)} \left\{ \frac{k^3 + 6k^2 + 9k + 4}{4(k+3)} \right\}$$

We can write it as

$$=\frac{1}{(k+1)(k+2)}\left\{\frac{k^3+2k^2+k+4k^2+8k+4}{4(k+3)}\right\}$$

Taking the common terms

$$= \frac{1}{(k+1)(k+2)} \left\{ \frac{k(k^2+2k+1)+4(k^2+2k+1)}{4(k+3)} \right\}$$

We get

$$= \frac{1}{(k+1)(k+2)} \left\{ \frac{k(k+1)^2 + 4(k+1)^2}{4(k+3)} \right\}$$

Here

$$= \frac{(k+1)^2 (k+4)}{4(k+1)(k+2)(k+3)}$$
$$= \frac{(k+1)\{(k+1)+3\}}{4\{(k+1)+1\}\{(k+1)+2\}}$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

12.

$$a + ar + ar^{2} + ... + ar^{n-1} = \frac{a(r^{n} - 1)}{r - 1}$$

We can write the given statement as

$$P(n): a + ar + ar^2 + ... + ar^{n-1} = \frac{a(r^n - 1)}{r - 1}$$

If n = 1 we get

$$P(1): a = \frac{a(r^1-1)}{(r-1)} = a$$

Which is true.

Consider P (k) be true for some positive integer k

$$a + ar + ar^{2} + \dots + ar^{k-1} = \frac{a(r^{k} - 1)}{r - 1}$$
 ... (i)

Now let us prove that P(k+1) is true.

Here

$$\{a+ar+ar^2+.....+ar^{k-1}\}+ar^{(k+1)-1}$$

By using equation (i)

$$= \frac{a(r^k - 1)}{r - 1} + ar^k$$

Taking LCM

$$=\frac{a(r^{k}-1)+ar^{k}(r-1)}{r-1}$$

Multiplying the terms

$$=\frac{a\left(r^{k}-1\right)+ar^{k+1}-ar^{k}}{r-1}$$

So we get

$$=\frac{ar^k-a+ar^{k+1}-ar^k}{r-1}$$

By further simplification

$$=\frac{ar^{k+1}-a}{r-1}$$

Taking the common terms out

$$=\frac{a\left(r^{k+1}-1\right)}{r-1}$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

13.

$$\left(1+\frac{3}{1}\right)\left(1+\frac{5}{4}\right)\left(1+\frac{7}{9}\right)...\left(1+\frac{(2n+1)}{n^2}\right)=\left(n+1\right)^2$$

Solution:

We can write the given statement as

$$P(n): \left(1 + \frac{3}{1}\right) \left(1 + \frac{5}{4}\right) \left(1 + \frac{7}{9}\right) \dots \left(1 + \frac{(2n+1)}{n^2}\right) = (n+1)^2$$

If n = 1 we get

$$P(1): (1+\frac{3}{1}) = 4 = (1+1)^2 = 2^2 = 4,$$

Which is true.

Consider P (k) be true for some positive integer k

$$\left(1+\frac{3}{1}\right)\left(1+\frac{5}{4}\right)\left(1+\frac{7}{9}\right)...\left(1+\frac{(2k+1)}{k^2}\right)=(k+1)^2 \qquad ... (1)$$

Now let us prove that P(k+1) is true.

Here

$$\left[\left(1+\frac{3}{1}\right)\left(1+\frac{5}{4}\right)\left(1+\frac{7}{9}\right)...\left(1+\frac{(2k+1)}{k^2}\right)\right]\left\{1+\frac{\left\{2(k+1)+1\right\}}{\left(k+1\right)^2}\right\}$$

By using equation (i)

$$= (k+1)^{2} \left(1 + \frac{2(k+1)+1}{(k+1)^{2}}\right)$$

Taking LCM

$$= (k+1)^{2} \left[\frac{(k+1)^{2} + 2(k+1) + 1}{(k+1)^{2}} \right]$$

So we get

$$=(k+1)^2+2(k+1)+1$$

By further simplification

$$=\{(k+1)+1\}^2$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

14.

$$\left(1+\frac{1}{1}\right)\left(1+\frac{1}{2}\right)\left(1+\frac{1}{3}\right)...\left(1+\frac{1}{n}\right)=(n+1)$$

We can write the given statement as

$$P(n): \left(1+\frac{1}{1}\right)\left(1+\frac{1}{2}\right)\left(1+\frac{1}{3}\right)...\left(1+\frac{1}{n}\right) = (n+1)$$

If n = 1 we get

$$P(1): (1+\frac{1}{1})=2=(1+1)$$

Which is true.

Consider P (k) be true for some positive integer k

$$P(k): \left(1 + \frac{1}{1}\right) \left(1 + \frac{1}{2}\right) \left(1 + \frac{1}{3}\right) \dots \left(1 + \frac{1}{k}\right) = (k+1)$$
 ... (1)

Now let us prove that P(k + 1) is true.

Here

$$\left[\left(1 + \frac{1}{1} \right) \left(1 + \frac{1}{2} \right) \left(1 + \frac{1}{3} \right) \dots \left(1 + \frac{1}{k} \right) \right] \left(1 + \frac{1}{k+1} \right)$$

By using equation (i)

$$= \left(k+1\right)\left(1+\frac{1}{k+1}\right)$$

Taking LCM

$$= (k+1) \left(\frac{(k+1)+1}{(k+1)} \right)$$

By further simplification

$$=(k+1)+1$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

15.

$$1^{2} + 3^{2} + 5^{2} + ... + (2n-1)^{2} = \frac{n(2n-1)(2n+1)}{3}$$

We can write the given statement as

$$P(n) = 1^2 + 3^2 + 5^2 + \dots + (2n-1)^2 = \frac{n(2n-1)(2n+1)}{3}$$

If n = 1 we get

$$P(1) = 1^2 = 1 = \frac{1(2.1-1)(2.1+1)}{3} = \frac{1.1.3}{3} = 1,$$

Which is true.

Consider P (k) be true for some positive integer k

$$P(k) = 1^2 + 3^2 + 5^2 + \dots + (2k-1)^2 = \frac{k(2k-1)(2k+1)}{3}$$
 ... (1)

Now let us prove that P(k+1) is true.

Here

$${1^2+3^2+5^2+...+(2k-1)^2}+{2(k+1)-1}^2$$

By using equation (i)

$$= \frac{k(2k-1)(2k+1)}{3} + (2k+2-1)^2$$

So we get

$$= \frac{k(2k-1)(2k+1)}{3} + (2k+1)^2$$

Taking LCM

$$=\frac{k(2k-1)(2k+1)+3(2k+1)^2}{3}$$

Taking the common terms out

$$=\frac{(2k+1)\{k(2k-1)+3(2k+1)\}}{3}$$

By further simplification

$$=\frac{(2k+1)\{2k^2-k+6k+3\}}{3}$$

So we get

$$=\frac{(2k+1)\{2k^2+5k+3\}}{3}$$

We can write it as

$$=\frac{(2k+1)\{2k^2+2k+3k+3\}}{3}$$

Splitting the terms

$$= \frac{(2k+1)\{2k(k+1)+3(k+1)\}}{2}$$

We get

$$=\frac{(2k+1)(k+1)(2k+3)}{3}$$

$$=\frac{(k+1)\{2(k+1)-1\}\{2(k+1)+1\}}{3}$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

$$\frac{1}{1.4} + \frac{1}{4.7} + \frac{1}{7.10} + \dots + \frac{1}{(3n-2)(3n+1)} = \frac{n}{(3n+1)}$$

Solution:

We can write the given statement as

$$P(n): \frac{1}{1.4} + \frac{1}{4.7} + \frac{1}{7.10} + \dots + \frac{1}{(3n-2)(3n+1)} = \frac{n}{(3n+1)}$$

If n = 1 we get

$$P(1) = \frac{1}{1.4} = \frac{1}{3.1+1} = \frac{1}{4} = \frac{1}{1.4}$$

Which is true.

Consider P (k) be true for some positive integer k

$$P(k) = \frac{1}{1.4} + \frac{1}{4.7} + \frac{1}{7.10} + \dots + \frac{1}{(3k-2)(3k+1)} = \frac{k}{3k+1}$$
 ... (1)

Now let us prove that P(k+1) is true.

Here

$$\left\{\frac{1}{1.4} + \frac{1}{4.7} + \frac{1}{7.10} + \dots + \frac{1}{(3k-2)(3k+1)}\right\} + \frac{1}{\{3(k+1)-2\}\{3(k+1)+1\}}$$

By using equation (i)

$$=\frac{k}{3k+1}+\frac{1}{(3k+1)(3k+4)}$$

So we get

$$=\frac{1}{(3k+1)}\left\{k+\frac{1}{(3k+4)}\right\}$$

Taking LCM

$$= \frac{1}{(3k+1)} \left\{ \frac{k(3k+4)+1}{(3k+4)} \right\}$$

Multiplying the terms

$$= \frac{1}{(3k+1)} \left\{ \frac{3k^2 + 4k + 1}{(3k+4)} \right\}$$

It can be written as

$$=\frac{1}{(3k+1)}\left\{\frac{3k^2+3k+k+1}{(3k+4)}\right\}$$

Separating the terms

$$=\frac{(3k+1)(k+1)}{(3k+1)(3k+4)}$$

By further calculation

$$=\frac{\left(k+1\right)}{3\left(k+1\right)+1}$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

17.
$$\frac{1}{3.5} + \frac{1}{5.7} + \frac{1}{7.9} + \dots + \frac{1}{(2n+1)(2n+3)} = \frac{n}{3(2n+3)}$$

We can write the given statement as

$$P(n): \frac{1}{3.5} + \frac{1}{5.7} + \frac{1}{7.9} + \dots + \frac{1}{(2n+1)(2n+3)} = \frac{n}{3(2n+3)}$$

If n = 1 we get

$$P(1): \frac{1}{3.5} = \frac{1}{3(2.1+3)} = \frac{1}{3.5}$$

Which is true.

Consider P (k) be true for some positive integer k

$$P(k): \frac{1}{3.5} + \frac{1}{5.7} + \frac{1}{7.9} + \dots + \frac{1}{(2k+1)(2k+3)} = \frac{k}{3(2k+3)}$$
 ... (1)

Now let us prove that P(k+1) is true.

Here

$$\left[\frac{1}{3.5} + \frac{1}{5.7} + \frac{1}{7.9} + \dots + \frac{1}{(2k+1)(2k+3)}\right] + \frac{1}{\{2(k+1)+1\}\{2(k+1)+3\}}$$

By using equation (i)

$$=\frac{k}{3(2k+3)}+\frac{1}{(2k+3)(2k+5)}$$

So we get

$$= \frac{1}{(2k+3)} \left[\frac{k}{3} + \frac{1}{(2k+5)} \right]$$

Taking LCM

$$= \frac{1}{(2k+3)} \left[\frac{k(2k+5)+3}{3(2k+5)} \right]$$

Multiplying the terms

$$= \frac{1}{(2k+3)} \left[\frac{2k^2 + 5k + 3}{3(2k+5)} \right]$$

It can be written as

$$= \frac{1}{(2k+3)} \left[\frac{2k^2 + 2k + 3k + 3}{3(2k+5)} \right]$$

Separating the terms

$$= \frac{1}{(2k+3)} \left[\frac{2k(k+1)+3(k+1)}{3(2k+5)} \right]$$

By further calculation

$$=\frac{(k+1)(2k+3)}{3(2k+3)(2k+5)}$$

$$=\frac{(k+1)}{3\{2(k+1)+3\}}$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

18

$$1+2+3+...+n<\frac{1}{8}(2n+1)^2$$

Solution:

We can write the given statement as

$$P(n): 1+2+3+...+n < \frac{1}{8}(2n+1)^2$$

If n = 1 we get

$$1 < \frac{1}{8}(2.1+1)^2 = \frac{9}{8}$$

Which is true.

Consider P (k) be true for some positive integer k

$$1+2+...+k < \frac{1}{8}(2k+1)^2$$
 ... (1)

Now let us prove that P(k + 1) is true.

Here

$$(1+2+...+k)+(k+1)<\frac{1}{8}(2k+1)^2+(k+1)$$

By using equation (i)

$$<\frac{1}{8}\left\{\left(2k+1\right)^2+8\left(k+1\right)\right\}$$

Expanding terms using formula

$$<\frac{1}{8}\left\{4k^2+4k+1+8k+8\right\}$$

By further calculation

$$<\frac{1}{8}\left\{4k^2+12k+9\right\}$$

So we get

$$<\frac{1}{8}(2k+3)^2$$

$$<\frac{1}{8}\{2(k+1)+1\}^2$$

$$(1+2+3+...+k)+(k+1)<\frac{1}{8}(2k+1)^2+(k+1)$$

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

19. n(n + 1)(n + 5) is a multiple of 3

Solution:

We can write the given statement as

P (n): n (n + 1) (n + 5), which is a multiple of 3

If n = 1 we get

1(1+1)(1+5) = 12, which is a multiple of 3 Which

is true.

Consider P (k) be true for some positive integer k

k(k+1)(k+5) is a multiple of 3

k (k + 1) (k + 5) = 3m, where $m \in N \dots (1)$

Now let us prove that P(k + 1) is true. Here

$$(k+1) \{(k+1)+1\} \{(k+1)+5\}$$

We can write it as

$$= (k + 1) (k + 2) \{(k + 5) + 1\}$$

By multiplying the terms

$$= (k + 1) (k + 2) (k + 5) + (k + 1) (k + 2)$$

So we get

$$= \{k (k + 1) (k + 5) + 2 (k + 1) (k + 5)\} + (k + 1) (k + 2)$$

Substituting equation (1)

$$=3m + (k + 1) \{2 (k + 5) + (k + 2)\}$$

By multiplication

$$=3m + (k + 1) \{2k + 10 + k + 2\}$$

On further calculation

$$=3m + (k + 1)(3k + 12)$$

Taking 3 as common

$$=3m+3(k+1)(k+4)$$

We get

$$= 3 \{m + (k+1)(k+4)\}$$

 $= 3 \times q$ where $q = \{m + (k + 1) (k + 4)\}$ is some natural number

$$(k+1) \{(k+1)+1\} \{(k+1)+5\}$$
 is a multiple of $3 P (k+1)$ is

true whenever P (k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

20. $10^{2n-1} + 1$ is divisible by 11 Solution:

We can write the given statement as

P (n):
$$10^{2^{n-1}} + 1$$
 is divisible by 11

If
$$n = 1$$
 we get

 $P(1) = 10^{2.1-1} + 1 = 11$, which is divisible by 11 Which

is true.

Consider P (k) be true for some positive integer k

$$10^{2k-1} + 1$$
 is divisible by 11

$$10^{2k-1} + 1 = 11m$$
, where $m \in \mathbb{N} \dots (1)$ Now

let us prove that P(k + 1) is true.

Here

 $10_{2(k+1)-1} + 1$

We can write it as

$$= 10_{2k+2-1} + 1$$

$$= 10_{2k+1} + 1$$

By addition and subtraction of 1

$$= 10^{2} (10^{2k-1} + 1 - 1) + 1$$

We get

$$= 10^{2} (10^{2k-1} + 1) - 10^{2} + 1$$

Using equation 1 we get

$$= 10^2$$
. $11m - 100 + 1$

$$= 100 \times 11m - 99$$

Taking out the common terms

$$= 11 (100m - 9)$$

= 11 r, where
$$r = (100m - 9)$$
 is some natural number

$$10^{2(k+1)-1} + 1$$
 is divisible by 11

P(k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

21. $x^{2n} - y^{2n}$ is divisible by x + y

Solution:

We can write the given statement as

P (n):
$$x^{2n} - y^{2n}$$
 is divisible by $x + y$

If
$$n = 1$$
 we get

P (1) =
$$x^{2 \times 1} - y^{2 \times 1} = x^2 - y^2 = (x + y)(x - y)$$
, which is divisible by $(x + y)$ Which

is true.

Consider P (k) be true for some positive integer k

$$x^{2k} - y^{2k}$$
 is divisible by $x + y$

$$x^{2k} - y^{2k} = m (x + y)$$
, where $m \in \mathbb{N}$ (1) Now

let us prove that P(k + 1) is true.

Here

$$X 2(k+1) = Y 2(k+1)$$

$$= x^{2k} \cdot x^2 - y^{2k} \cdot y^2$$

By adding and subtracting y^{2k} we get

$$= x^{2} (x^{2k} - y^{2k} + y^{2k}) - y^{2k} \cdot y^{2}$$

From equation (1) we get

$$= x^{2} \{m(x + y) + y^{2k}\} - y^{2k}. y^{2k}$$

By multiplying the terms

$$= m (x + y) x^2 + y^{2k} \cdot x^2 - y^{2k} \cdot y^2$$

Taking out the common terms

$$= m (x + v) x^2 + v^{2k} (x^2 - v^2)$$

Expanding using formula

$$= m (x + y) x^{2} + y^{2k} (x + y) (x - y)$$

So we get

= $(x + y) \{mx^2 + y^{2k} (x - y)\}$, which is a factor of (x + y) P (k + 1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

22. $3^{2n+2} - 8n - 9$ is divisible by 8

Solution:

We can write the given statement as

P (n): $3^{2n+2} - 8n - 9$ is divisible by 8

If n = 1 we get

 $P(1) = 3^{2 \times 1 + 2} - 8 \times 1 - 9 = 64$, which is divisible by 8 Which

is true.

Consider P (k) be true for some positive integer k

 $3^{2k+2} - 8k - 9$ is divisible by 8

 $3^{2^{k+2}} - 8k - 9 = 8m$, where $m \in \mathbb{N}$ (1) Now

let us prove that P(k + 1) is true.

Here

$$3_{2(k+1)+2}-8(k+1)-9$$

We can write it as

$$=3^{2k+2} \cdot 3^2 - 8k - 8 - 9$$

By adding and subtracting 8k and 9 we get

$$=3^{2}(3^{2k+2}-8k-9+8k+9)-8k-17$$

On further simplification

$$= 3^{2} (3^{2k+2} - 8k - 9) + 3^{2} (8k + 9) - 8k - 17$$

From equation (1) we get

$$= 9.8m + 9(8k + 9) - 8k - 17$$

By multiplying the terms

$$= 9.8m + 72k + 81 - 8k - 17$$

So we get

$$= 9.8m + 64k + 64$$

By taking out the common terms

$$= 8 (9m + 8k + 8)$$

=
$$8r$$
, where $r = (9m + 8k + 8)$ is a natural number

So
$$3^{2(k+1)+2} - 8(k+1) - 9$$
 is divisible by 8 P (k

+ 1) is true whenever P (k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

23. $41^n - 14^n$ is a multiple of 27

Solution:

We can write the given statement as

 $P(n):41^{n} - 14^{n}$ is a multiple of 27

If n = 1 we get

 $P(1) = 41^1 - 14^1 = 27$, which is a multiple by 27

Which is true.

Consider P (k) be true for some positive integer k

 $41^k - 14^k$ is a multiple of 27

 $41^k - 14^k = 27m$, where $m \in \mathbb{N}$ (1) Now

let us prove that P(k+1) is true.

Here

 $41_{k+1} - 14_{k+1}$

We can write it as =

 41^k . $41 - 14^k$. 14

By adding and subtracting 14^k we get

 $=41 (41^k - 14^k + 14^k) - 14^k$. 14

On further simplification

 $=41 (41^{k} - 14^{k}) + 41.14^{k} - 14^{k}.14$

From equation (1) we get

 $=41.27m + 14^{k} (41 - 14)$

By multiplying the terms

 $=41.27m + 27.14^{k}$

By taking out the common terms

 $= 27 (41m - 14^k)$

= 27r, where $r = (41m - 14^k)$ is a natural number

So $41^{k+1} - 14^{k+1}$ is a multiple of 27 P

(k + 1) is true whenever P (k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.

24. $(2n+7) < (n+3)^2$ Solution:

We can write the given statement as

P(n): (2n +7) < (n + 3)2

If n = 1 we get

 $2.1 + 7 = 9 < (1 + 3)^2 = 16$ Which

is true

Consider P (k) be true for some positive integer k

 $(2k+7) < (k+3)^2 \dots (1)$

Now let us prove that P(k + 1) is true.

Here

 ${2(k+1)+7} = (2k+7)+2$

We can write it as

$$= \{2(k+1)+7\}$$

From equation (1) we get

$$(2k + 7) + 2 < (k + 3)^2 + 2$$

By expanding the terms

$$2(k+1) + 7 < k^2 + 6k + 9 + 2$$

On further calculation

$$2(k+1) + 7 < k^2 + 6k + 11$$

Here $k^2 + 6k + 11 < k^2 + 8k + 16$ We can write it as $2(k+1) + 7 < (k+4)^2$ $2(k+1) + 7 < \{(k+1) + 3\}^2$ P(k+1) is true whenever P(k) is true.

Therefore, by the principle of mathematical induction, statement P (n) is true for all natural numbers i.e. n.
